(Received)

We study the conductance of disordered wires with unitary symmetry focusing on the case in which m perfectly conducting channels are present due to the channel-number imbalance between two-propagating directions. Using the exact solution of the Dorokhov-Mello-Pereyra-Kumar (DMPK) equation for transmission eigenvalues, we obtain the average and second moment of the conductance in the long-wire regime. For comparison, we employ the three-edge Chalker-Coddington model as the simplest example of channel-number-imbalanced systems with $m = 1$, and obtain the average and second moment of the conductance by using a supersymmetry approach. We show that the result for the Chalker-Coddington model is identical to that obtained from the DMPK equation.

KEYWORDS: unitary class, DMPK equation, Chalker-Coddington model, supersymmetry

1. Introduction

The statistical property of electron transport in a disordered quantum wire is independent of microscopic details of the system, and is mainly determined by the symmetries the system possesses.¹ In ordinary disordered systems, only time-reversal and spin-rotation symmetries play a relevant role. According to the presence or absence of these two symmetries, disordered quantum wires are classified into either of the three standard universality classes (i.e., orthogonal, unitary and symplectic). The orthogonal class consists of systems having both time-reversal and spin-rotation symmetries, while the unitary class is characterized by the absence of time-reversal symmetry. The systems having time reversal-symmetry without spin-rotation symmetry belong to the symplectic class. It has been believed that although details of transport properties differ from class to class, Anderson localization inevitably arises in all the three standard classes (i.e., the conductance decays exponentially with increasing sample length L and eventually vanishes in the limit of $L \rightarrow \infty$). However, this widely accepted understanding does not always hold true. Recent studies on the symplectic universality class show that if the number of conducting channels is odd, one channel becomes perfectly conducting without backward scattering.²⁻⁸ Due to the presence of this perfectly conducting channel, the dimensionless conductance behaves as $g \rightarrow 1$ with increasing L , and thereby Anderson localization disappears. In contrast to this, such an anomalous behavior does not arise

in the ordinary case with an even number of conducting channels. Thus, we must separate the symplectic class into two subclasses of symplectic-even and symplectic-odd according to whether the number of conducting channels is even or odd.^{3,7}

The realization of the symplectic-odd class revives attention to disordered wire systems with the channel-number imbalance between two-propagating directions. More than a decade ago, Barnes, Johnson and Kirczenow⁹ pointed out that if the number of conducting channels in one propagating direction is by m greater than that in the opposite direction, the dimensionless conductances g for the majority direction and g' for the minority direction satisfy $g = g' + m$. Performing a numerical simulation, they obtained evidence that $g \rightarrow m$ and $g' \rightarrow 0$ in the long- L limit. This indicates that m perfectly conducting channels are present only in the majority direction. Note that the channel-number imbalance leads to the breaking of time-reversal symmetry, so that their argument applies only to the unitary class. Recently, Hirose, Ohtuski and Slevin¹⁰ have proposed the Chalker-Coddington model¹¹ with an odd-number of edge channels and studied its electron transport properties. The Chalker-Coddington model can be viewed as a stacking of alternating left-moving and right-moving chiral edge channels with random tunneling between adjacent ones.¹² It should be noted that in the odd-edge case, the channel number in one propagating direction is by one greater than that in the opposite direction. This situation is equivalent to that in the case of $m = 1$ considered in ref. 9. Performing a numerical simulation, they also confirmed that $g \rightarrow 1$ and $g' \rightarrow 0$ in the long- L limit.

One may think that the channel-number imbalance is rather unrealistic in actual systems. However, Wakabayashi *et al.*¹³ have recently shown that such a system can be realized in zigzag nanographene ribbons.¹⁴ Inspired by this observation, the present author and Wakabayashi¹⁵ have formulated a random-matrix theory for the unitary universality class with the channel-number imbalance. Let us focus on a disordered wire system of length L having $N + m$ left-moving channels and N right-moving channels. In this case, m left-moving channels become perfectly conducting and the dimensionless conductances g and g' for the left-moving and right-moving channels, respectively, satisfy $g = g' + m$. They have derived the Dorokhov-Mello-Pereyra-Kumar (DMPK) equation, which describes the evolution of the probability distribution for transmission eigenvalues with increasing L ,^{16,17} and analyzed the asymptotic behavior of $g' = g - m$ in the long- L regime by using an approximate method proposed by Pichard.¹⁸ They have shown that the localization length ξ , which characterizes the exponential decay of $\exp[\langle \ln g' \rangle]$, depends on m as $\xi = 2Nl/(m + 1)$, where l is the mean free path for the left-moving channels. That is, ξ decreases with increasing the number m of perfectly conducting channels. This means that the presence of perfectly conducting channels suppresses g' . Furthermore, they have also shown that the average and second moment of g' behave as $\langle g' \rangle \sim e^{-\frac{s}{4N}}$ for $m = 0$, $\langle g' \rangle \sim e^{-\frac{ms}{N}}$ for $m \geq 1$, $\langle g'^2 \rangle \sim e^{-\frac{(m+1)^2 s}{4N}}$ for $0 \leq m \leq 3$,

and $\langle g'^2 \rangle \sim e^{-\frac{2(m-1)s}{N}}$ for $m \geq 3$, where $s \equiv L/l$. To examine these results in terms of an independent approach, the present author and Wakabayashi¹⁹ have studied the averaged conductance $\langle g' \rangle$ in the three-edge Chalker-Coddington model, i.e., the simplest nontrivial example of the channel-number-imbalanced unitary class with $m = 1$. They have found that $\langle g' \rangle \sim e^{-\frac{s}{N}}$, which is consistent with the DMPK result. Although this supports the validity of the DMPK approach, a more detailed comparison is highly desirable to deeply understand the nature of this peculiar universality class.

In this paper, we study the average and second moment of the dimensionless conductance g' for the channel-number-imbalanced unitary class. First, we obtain the asymptotic forms of $\langle g' \rangle$ and $\langle g'^2 \rangle$ in the long- L regime for $0 \leq m \leq 4$ by using the existing exact solution²⁰ of the DMPK equation. The exact solution, which is available only in the unitary class,²¹ enables us to obtain the full asymptotic forms including a pre-exponential factor.²² Second, we employ the M -edge Chalker-Coddington model for the cases of $M = 2$ and $M = 3$, and obtain $\langle g' \rangle$ and $\langle g'^2 \rangle$ in the long- L regime by using a supersymmetry approach.²³ The $M = 2$ case is the simplest example of the ordinary unitary class, while the $M = 3$ case is that of the channel-number-imbalanced unitary class. We obtain the full asymptotic forms of $\langle g' \rangle$ and $\langle g'^2 \rangle$ including a pre-exponential factor. We show that the resulting asymptotic forms are identical to those obtained from the DMPK equation. This strongly supports the validity of the DMPK approach.

In the next section, we introduce the DMPK equation for the channel-number-imbalanced unitary class and introduce its exact solution. We obtain the average $\langle g' \rangle$ and second moment $\langle g'^2 \rangle$ of the dimensionless conductance g' in the long- L regime using the exact solution. In §3, we introduce the M -edge Chalker-Coddington model and obtain $\langle g' \rangle$ and $\langle g'^2 \rangle$ for the cases of $M = 2$ and $M = 3$. Section 4 is devoted to summary.

2. DMPK Approach

We summarize the random-matrix theory for the channel-number-imbalanced unitary class.¹⁵ We consider the case in which the number of left-moving channels is $N + m$, while that of right-moving channels is N . In this case, we can show that m transmission eigenvalues in the left-moving channels become unity.^{9,10,15} This indicates the presence of perfectly conducting channels. If the set of the transmission eigenvalues for the right-moving channels is $\{T_1, T_2, \dots, T_N\}$, that for the left-moving channels is expressed as $\{T_1, T_2, \dots, T_N, 1, \dots, 1\}$, where we have identified the $N + 1$ to $N + m$ th channels as the perfectly conducting ones. The dimensionless conductance g for the left-moving channels is given by $g = \sum_{a=1}^{N+m} T_a = m + \sum_{a=1}^N T_a$, while that for the right-moving channels is $g' = \sum_{a=1}^N T_a$. It is easy to observe that $g = g' + m$. We consider the behavior of $g' = g - m$ as a function of the normalized system length $s \equiv L/l$, where l is the mean free path for the left-moving channels. It should be noted that the mean free path l' for the right-moving channels is not

equal to l due to the presence of perfectly conducting channels only in the left-moving channels. Indeed, we find that $l' = (N/(N+m))l$. We define $\lambda_a \equiv (1 - T_a)/T_a$ and introduce the probability distribution $P(\{\lambda_a\}; s)$ for the transmission eigenvalues. The Fokker-Planck equation for $P(\{\lambda_a\}; s)$, which is usually called the DMPK equation, is expressed as¹⁵

$$\frac{\partial P(\{\lambda_a\}; s)}{\partial s} = \frac{1}{N} \sum_{a=1}^N \frac{\partial}{\partial \lambda_a} \left(\lambda_a (1 + \lambda_a) J \frac{\partial}{\partial \lambda_a} \left(\frac{P(\{\lambda_a\}; s)}{J} \right) \right) \quad (1)$$

with

$$J = \prod_{c=1}^N \lambda_c^m \times \prod_{b=1}^{N-1} \prod_{a=b+1}^N |\lambda_a - \lambda_b|^2. \quad (2)$$

As stressed in ref. 15, the factor $\prod_{c=1}^N \lambda_c^m$ in J represents the repulsion arising from the m -fold degenerate perfectly conducting eigenvalue. This reduces the non-perfectly conducting eigenvalues $\{T_1, T_2, \dots, T_N\}$. It should be mentioned that the equivalent DMPK equation was proposed by Akuzawa and Wadati²⁰ in a rather formal context, but they did not study electron transport properties.

The DMPK equation has been solved exactly for the ordinary case of $m = 0$.^{21,22} The exact solution for an arbitrary m has been obtained in ref. 20. In our notation, the probability distribution is given by

$$P(\{\lambda_a\}; s) = \frac{1}{N!} \text{Det} \{K(\lambda_a, \lambda_b; s)\}_{a,b=1,2,\dots,N} \quad (3)$$

with

$$K(\lambda, \lambda'; s) = \sum_{j=1}^N Q_j(\lambda, s) h_j(\lambda', s). \quad (4)$$

Here,

$$Q_j(\lambda, s) = \lambda^m G_{j-1}(m+1, m+1; -\lambda) e^{-\frac{(2j+m-1)^2}{4N} s}, \quad (5)$$

$$h_j(\lambda, s) = \int_0^\infty dk L_j(k) c_m^2(k) e^{-\frac{k^2}{4N} s} F\left(\frac{m+1-ik}{2}, \frac{m+1+ik}{2}, m+1; -\lambda\right), \quad (6)$$

where $G_{j-1}(m+1, m+1; -\lambda) \equiv F(-j+1, m+j, m+1; -\lambda)$ is the Jacobi polynomial and

$$L_j(k) = \prod_{l=1(l \neq j)}^N \frac{k^2 + (2l+m-1)^2}{-(2j+m-1)^2 + (2l+m-1)^2}, \quad (7)$$

$$c_m(k) = \frac{1}{\sqrt{4\pi}} \frac{\Gamma\left(\frac{m+1+ik}{2}\right) \Gamma\left(\frac{m+1-ik}{2}\right)}{\Gamma(m+1) |\Gamma(ik)|}. \quad (8)$$

Note that $K(\lambda, \lambda'; s)$ satisfies

$$\int_0^\infty d\lambda K(\lambda, \lambda; s) = N, \quad (9)$$

$$\int_0^\infty d\lambda'' K(\lambda, \lambda''; s) K(\lambda'', \lambda'; s) = K(\lambda, \lambda'; s). \quad (10)$$

Using these equations, we obtain the eigenvalue density

$$\begin{aligned} R_1(\lambda_1; s) &= N \int_0^\infty d\lambda_2 \cdots d\lambda_N P(\{\lambda_a\}; s) \\ &= K(\lambda_1, \lambda_1; s), \end{aligned} \quad (11)$$

and the two-point correlation function

$$\begin{aligned} R_2(\lambda_1, \lambda_2; s) &= N(N-1) \int_0^\infty d\lambda_3 \cdots d\lambda_N P(\{\lambda_a\}; s) \\ &= K(\lambda_1, \lambda_1; s)K(\lambda_2, \lambda_2; s) - K(\lambda_1, \lambda_2; s)K(\lambda_2, \lambda_1; s). \end{aligned} \quad (12)$$

We focus on the dimensionless conductance g' for the right-moving channels, in terms of which the dimensionless conductance g for the left-moving channels is given by $g = m + g'$. Using the eigenvalue density, we express the averaged dimensionless conductance as

$$\langle g' \rangle = \int_0^\infty d\lambda \frac{1}{1+\lambda} R_1(\lambda; s). \quad (13)$$

Using the eigenvalue density and the two-point correlation function, we express the second moment as

$$\langle g'^2 \rangle = \int_0^\infty d\lambda \frac{1}{(1+\lambda)^2} R_1(\lambda; s) + \int_0^\infty d\lambda \int_0^\infty d\lambda' \frac{1}{(1+\lambda)(1+\lambda')} R_2(\lambda, \lambda'; s). \quad (14)$$

Alternatively, once $\langle g' \rangle$ is given, $\langle g'^2 \rangle$ is obtained by using the scaling relation

$$N \frac{\partial \langle g' \rangle}{\partial s} = -\langle g'^2 \rangle - m \langle g' \rangle, \quad (15)$$

which can be derived from eq. (1) (see Appendix A). Using these equations, we obtain $\langle g' \rangle$ and $\langle g'^2 \rangle$ in the asymptotic regime of $s \equiv L/l \gg 4N$. It should be mentioned that the ordinary case of $m = 0$ has been analyzed in ref. 22.

We obtain the asymptotic form of $\langle g' \rangle$. We rewrite eq. (13) as

$$\langle g' \rangle = \int_0^\infty d\lambda \frac{1}{1+\lambda} \sum_{j=1}^N Q_j(\lambda, s) h_j(\lambda, s). \quad (16)$$

From eq. (5), we observe that the term with $j = 1$ dominates the others in the asymptotic regime of $s \gg 4N$, so that we can neglect the terms with $j \geq 2$. Equation (16) is then reduced to

$$\begin{aligned} \langle g'_m \rangle &= \int_0^\infty d\lambda \frac{\lambda^m}{1+\lambda} \int_0^\infty dk L_1(k) c_m^2(k) e^{-\frac{k^2 + (m+1)^2}{4N} s} \\ &\quad \times F\left(\frac{m+1-ik}{2}, \frac{m+1+ik}{2}, m+1; -\lambda\right), \end{aligned} \quad (17)$$

where $G_0(m+1, m+1; -\lambda) = 1$ has been used. Here and hereafter, we explicitly show the number of perfectly conducting channels as a subscript. Before describing the evaluation of

eq. (17), we present the final results,

$$\langle g'_0 \rangle = \frac{\pi^{\frac{3}{2}}}{4} a_N \frac{1}{\sqrt{\frac{s}{4N}}^3} e^{-\frac{s}{4N}}, \quad (18)$$

$$\langle g'_1 \rangle = \frac{2}{\pi^{\frac{3}{2}}} a_N \frac{1}{\sqrt{\frac{s}{4N}}} e^{-\frac{s}{N}}, \quad (19)$$

$$\langle g'_2 \rangle = \frac{1}{8} a_N e^{-\frac{2s}{N}}, \quad (20)$$

$$\langle g'_3 \rangle = \frac{1}{6\pi} a_N e^{-\frac{3s}{N}}, \quad (21)$$

$$\langle g'_4 \rangle = \frac{9}{512} a_N e^{-\frac{4s}{N}}, \quad (22)$$

where

$$a_N = \frac{\pi}{4} L_1(0) = \frac{\Gamma(N + \frac{1}{2})^2}{N!(N-1)!}. \quad (23)$$

Note that $a_1 = \pi/4$ and $\lim_{N \rightarrow \infty} a_N = 1$. We observe that the exponential decay of $\langle g'_m \rangle$ becomes faster with increasing m . This should be attributed to the eigenvalue repulsion arising from the m -fold degenerate perfectly conducting eigenvalue.

We briefly describe the derivation of eqs. (18)-(22). For the cases of $m = 0$ and $m = 1$, we can exchange the order of the integrations over λ and k in eq. (17) and find

$$\langle g'_m \rangle = \int_0^\infty dk L_1(k) c_m^2(k) e^{-\frac{k^2 + (m+1)^2}{4N} s} I_m(k) \quad (24)$$

with

$$I_m(k) = \int_0^\infty d\lambda \frac{\lambda^m}{1+\lambda} F\left(\frac{m+1-ik}{2}, \frac{m+1+ik}{2}, m+1; -\lambda\right). \quad (25)$$

Adapting the method presented in ref. 24, we analytically obtain $I_m(k)$ as

$$I_0(k) = \frac{\pi}{\cosh\left(\frac{\pi k}{2}\right)}, \quad (26)$$

$$I_1(k) = \frac{2\pi}{k \sinh\left(\frac{\pi k}{2}\right)}. \quad (27)$$

We next carry out the integration over k in eq. (24). The main contribution comes from the small- k region of $k \lesssim \sqrt{4N/s}$, and therefore we approximate as $L_1(k) = L_1(0)$, $c_0^2(k) = (\pi/4)k^2$, $c_1^2(k) = (4\pi)^{-1}k^2$, $I_0(k) = \pi$ and $I_1(k) = 4/k^2$. After the k -integration, we finally obtain eqs. (18) and (19). For $m \geq 2$, we employ a different approach, which is applicable to the cases of $m \geq 1$. We consider eq. (17) in the large- s limit. Expecting that the main contribution to the λ -integration comes from the region of $\lambda \gg 1$, we replace the hypergeometric function in eq. (17) by its asymptotic form

$$F\left(\frac{m+1-ik}{2}, \frac{m+1+ik}{2}, m+1; -\lambda\right) = \frac{\Gamma(m+1)\Gamma(ik)}{\Gamma\left(\frac{m+1+ik}{2}\right)^2} \lambda^{-\frac{m+1-ik}{2}} + \text{c.c.} \quad (28)$$

in the large- λ limit. We treat the case of $m = 1$ as an example. Note that the main contribution to the k -integration comes from the region of $k \lesssim \sqrt{4N/s}$, in which we can approximate as $L_1(k) = L_1(0)$ and $c_1^2(k) = (4\pi)^{-1}k^2$, and eq. (28) with $m = 1$ is reduced to

$$F\left(\frac{2-ik}{2}, \frac{2+ik}{2}, 2; -\lambda\right) = 2\lambda^{-1} \frac{\sin\left(k\frac{\ln\lambda}{2}\right)}{k}. \quad (29)$$

After the k -integration, we obtain

$$\langle g'_1 \rangle = \frac{L_1(0)}{8\sqrt{\pi}} \frac{1}{\sqrt{\frac{s}{4N}}^3} e^{-\frac{s}{N}} \int_0^\infty d\lambda \frac{1}{1+\lambda} \frac{\ln\lambda}{2} \exp\left(-\frac{N}{s} \left(\frac{\ln\lambda}{2}\right)^2\right). \quad (30)$$

Changing the variable from λ to x defined by $\lambda = (\cosh(2x) - 1)/2$, we obtain

$$\int_0^\infty d\lambda \frac{1}{1+\lambda} \frac{\ln\lambda}{2} \exp\left(-\frac{N}{s} \left(\frac{\ln\lambda}{2}\right)^2\right) \approx 2 \int_0^\infty dx x e^{-\frac{N}{s}x^2} = \frac{s}{N}. \quad (31)$$

Substituting this into eq. (30) and using $L_1(0) = (4/\pi)a_N$, we again arrive at eq. (19). Adapting the above method to the cases of $m \geq 2$, we obtain eqs. (20)-(22).

We turn to the evaluation of the second moment in the asymptotic regime. The results are summarized as follows:

$$\langle g'^2_0 \rangle = \frac{\pi^{\frac{3}{2}}}{16} a_N \frac{1}{\sqrt{\frac{s}{4N}}^3} e^{-\frac{s}{4N}}, \quad (32)$$

$$\langle g'^2_1 \rangle = \frac{1}{4\pi^{\frac{3}{2}}} a_N \frac{1}{\sqrt{\frac{s}{4N}}^3} e^{-\frac{s}{N}}, \quad (33)$$

$$\langle g'^2_2 \rangle = \frac{\pi^{\frac{3}{2}}}{128} a_N \frac{1}{\sqrt{\frac{s}{4N}}^3} e^{-\frac{9s}{4N}}, \quad (34)$$

$$\langle g'^2_3 \rangle = \frac{1}{3\pi^{\frac{3}{2}}} a_N \frac{1}{\sqrt{\frac{s}{4N}}^3} e^{-\frac{4s}{N}}, \quad (35)$$

$$\langle g'^2_4 \rangle = \frac{3}{128} a_N e^{-\frac{6s}{N}}. \quad (36)$$

Again, we observe that the decay of $\langle g'^2_m \rangle$ becomes faster with increasing m due to the eigenvalue repulsion from the m -fold degenerate perfectly conducting eigenvalue.

We briefly present the derivation of eqs. (32)-(36). From eq. (15), the second moment is expressed in terms of the averaged conductance as

$$\langle g'^2_m \rangle = -N \frac{\partial \langle g'_m \rangle}{\partial s} - m \langle g'_m \rangle. \quad (37)$$

Substituting eqs. (18) and (19) into this, we straightforwardly obtain eqs. (32) and (33), respectively. However, the right-hand side of eq. (37) vanishes if we substitute eqs. (20)-(22). This means that the second moment for $m \geq 2$ is related to the next leading order correction to $\langle g'_m \rangle$. Instead of evaluating such a correction, we directly obtain $\langle g'^2_m \rangle$ using eq. (14). In

the asymptotic regime, eq. (14) is approximately reduced to

$$\langle g'^2_m \rangle = \int_0^\infty d\lambda \frac{\lambda^m}{(1+\lambda)^2} \int_0^\infty dk L_1(k) c_m^2(k) e^{-\frac{k^2+(m+1)^2}{4N}s} \times F\left(\frac{m+1-ik}{2}, \frac{m+1+ik}{2}, m+1; -\lambda\right). \quad (38)$$

When $m \leq 3$, we can exchange the order of the λ - and k -integrations and find

$$\langle g'^2 \rangle = \int_0^\infty dk L_1(k) c_m^2(k) e^{-\frac{k^2+(m+1)^2}{4N}s} \tilde{I}_m(k) \quad (39)$$

with

$$\tilde{I}_m(k) = \int_0^\infty d\lambda \frac{\lambda^m}{(1+\lambda)^2} F\left(\frac{m+1-ik}{2}, \frac{m+1+ik}{2}, m+1; -\lambda\right). \quad (40)$$

Adapting the method presented in ref. 24, we can analytically obtain $\tilde{I}_m(k)$ as

$$\tilde{I}_2(k) = \frac{2\pi}{\cosh\left(\frac{\pi k}{2}\right)}, \quad (41)$$

$$\tilde{I}_3(k) = \frac{12\pi}{k \sinh\left(\frac{\pi k}{2}\right)}. \quad (42)$$

After carrying out the integration over k , we obtain eqs. (34) and (35). This approach cannot be applied when $m \geq 4$, so we adapt the method used to derive eqs. (20)-(22). It is applicable to the cases of $m \geq 3$. We replace the hypergeometric function in eq. (38) by its asymptotic form and integrate over k . For $m = 4$, we obtain

$$\langle g'^2_4 \rangle = \frac{3\sqrt{\pi}L_1(0)}{4^5} \frac{1}{\sqrt{\frac{s}{4N}}^3} e^{-\frac{25s}{4N}} \int_0^\infty d\lambda \frac{\lambda^{\frac{3}{2}}}{(1+\lambda)^2} \frac{\ln \lambda}{2} \exp\left(-\frac{N}{s} \left(\frac{\ln \lambda}{2}\right)^2\right). \quad (43)$$

After the λ -integration, we finally arrive at eq. (36).

3. Chalker-Coddington Model

We consider an electron system consisting of M chiral edge channels as shown in Fig. 1. The propagating direction of the j th edge channel is left (right) if j is odd (even), and each edge is coupled with adjacent counter-propagating edge(s) by random tunneling. Note that this system is essentially equivalent to the Chalker-Coddington model. We assume that the electron wavefunction $\phi_j(x)$ for the j th edge channel with energy ε obeys^{12,23}

$$(-1)^j (-i) \partial_x \phi_j(x) + t_j(x) \phi_{j+1}(x) + t_{j-1}^*(x) \phi_{j-1}(x) = \varepsilon \phi_j(x), \quad (44)$$

where $\phi_0(x) = \phi_{M+1}(x) \equiv 0$ has been assumed. Here, $t_j(x)$ and $t_j^*(x)$ represent the tunneling amplitude from the j th edge to $j+1$ th edge and that for the reverse process, respectively. We assume that $\{t_j(x)\}$ are random variables in the disordered region of $0 < x < L$, and vanish outside this region. We regard L as the length of our system, and the clean regions of $x \leq 0$ and $L \leq x$ play a role of the left and right electrodes, respectively. The random amplitudes in the disordered region are assumed to be Gaussian distributed with zero means. That is, $\langle t_j(x) \rangle = 0$, $\langle t_j(x) t_{j'}(x') \rangle = 0$ and

$$\langle t_j(x) t_{j'}^*(x') \rangle = D \delta_{j,j'} \delta(x - x'), \quad (45)$$

Fig. 1. Schematic sketch of the Chalker-Coddington model for (a) the two-edge case of $M = 2$ and (b) the three-edge case of $M = 3$.

where $\langle \cdots \rangle$ represents the ensemble average. We hereafter set $\varepsilon = 0$ without loss of generality.

The dimensionless conductance g for the left-moving channels is expressed as $g = \sum_{i,j=\text{odd}} \mathcal{T}_{ij}$, where $\mathcal{T}_{ij}$ is the transmission probability for an electron incoming from the j th channel in the right electrode and outgoing to the i th channel in the left electrode. In a manner similar to this, g' for the right-moving channels is expressed as $g' = \sum_{i,j=\text{even}} \mathcal{T}_{ij}$. The dimensionless conductances satisfy $g = g'$ in the ordinary case of an even M . In the odd- M case, which is first studied by Hirose, Ohtuski and Slevin,¹⁰ the number of the left-moving channels is by one greater than that of the right-moving channels, so that one left-moving channel becomes perfectly conducting. In this case, we observe that $g = 1 + g'$. We consider the two-edge case of $M = 2$ and the three-edge case of $M = 3$ in the following. In the notation used in the previous section, the former and latter correspond to the cases of $N = 1$ with $m = 0$ and $N = 1$ with $m = 1$, respectively. The three-edge case of $M = 3$ is the simplest nontrivial example of the disordered wires with the channel-number imbalance. Hereafter, we again explicitly show the number m of perfectly conducting channels as a subscript of g' . We focus on the average and second moment of g'_m ($m = 0, 1$) as a function of L . Note that $g'_m = \mathcal{T}_{22}$ in the two- and three-edge cases, in which only one right-moving channel exists.

Mathur has shown for the $M = 2$ case that^{23, 25}

$$\langle g'_0 \rangle = \frac{\pi^{\frac{5}{2}}}{16} \frac{1}{\sqrt{\frac{DL}{4}}}^3 e^{-\frac{DL}{4}} \quad (46)$$

in the asymptotic regime of $DL \gg 1$. This result is identical to eq. (18) in the case of $N = 1$ if we replace DL by s . This indicates that D^{-1} should be identified with the mean free path $\tilde{l}$ for the $M = 2$ case. In the $M = 3$ case, each left-moving edge channel is directly coupled to one right-moving edge channel as in the case of $M = 2$, so the mean free path for the left direction

is equal to $\tilde{l}$ under the condition of eq. (45). However, because the right-moving channel interacts with the two left-moving channels, the corresponding mean free path becomes half of $\tilde{l}$. Thus, for comparison with the argument in §2, in which the system length is normalized by the mean free path for the left-moving channels, we hereafter adopt D^{-1} as the unit length scale common to both the cases of $M = 2$ and 3. This is simply achieved by the replacement $DL \rightarrow s$.

We obtain the asymptotic forms of $\langle g_0'^2 \rangle$, $\langle g_1' \rangle$ and $\langle g_1'^2 \rangle$ by adapting the supersymmetry approach presented by Mathur.²³ The supersymmetry approach enables us to express the average and second moment of the transmission probability in the form of a correlation function for a non-random interacting fermion-boson system on a one-dimensional chain. For the two-edge (three-edge) case, we need to consider the two-site (three-site) chain which we describe below. Let $c_{i\sigma}$ ($c_{i\sigma}^\dagger$) be the fermion annihilation (creation) operator, and $b_{i\sigma}$ ($b_{i\sigma}^\dagger$) be the boson annihilation (creation) operator, where $i = 1, 2, 3$ represents the site number and $\sigma = \uparrow, \downarrow$. The sites are one-to-one correspondence with the edge channels in the original model. The Hamiltonian H for the two-edge case is identical to H_{12} which represents the interaction between the 1st and 2nd sites. The Hamiltonian for the three-edge case is given by $H = H_{12} + H_{23}$, where H_{23} represents the interaction between the 2nd and 3rd sites. The explicit form of H_{12} is given by $H_{12} = H_{12}^F + H_{12}^B + H_{12}^{FB}$ with

$$H_{12}^F = - \sum_{\sigma=\uparrow,\downarrow} \left(c_{1\sigma}^\dagger c_{1\sigma} - 1/2 \right) \left(c_{2\sigma}^\dagger c_{2\sigma} - 1/2 \right) + c_{1\uparrow}^\dagger c_{1\downarrow}^\dagger c_{2\uparrow}^\dagger c_{2\downarrow}^\dagger + c_{1\downarrow} c_{1\uparrow} c_{2\downarrow} c_{2\uparrow}, \quad (47)$$

$$H_{12}^B = \sum_{\sigma=\uparrow,\downarrow} \left(b_{1\sigma}^\dagger b_{1\sigma} + 1/2 \right) \left(b_{2\sigma}^\dagger b_{2\sigma} + 1/2 \right) - b_{1\uparrow}^\dagger b_{1\downarrow}^\dagger b_{2\uparrow}^\dagger b_{2\downarrow}^\dagger - b_{1\downarrow} b_{1\uparrow} b_{2\downarrow} b_{2\uparrow}, \quad (48)$$

$$H_{12}^{FB} = \sum_{\sigma=\uparrow,\downarrow} \left(-c_{1\sigma}^\dagger b_{1\sigma} c_{2\sigma}^\dagger b_{2\sigma} - c_{1\sigma} b_{1\sigma}^\dagger c_{2\sigma} b_{2\sigma}^\dagger + c_{1\sigma}^\dagger b_{1\bar{\sigma}} c_{2\sigma}^\dagger b_{2\bar{\sigma}}^\dagger + c_{1\sigma} b_{1\bar{\sigma}} c_{2\sigma} b_{2\bar{\sigma}} \right), \quad (49)$$

where $\bar{\sigma}$ in eq. (49) means $\bar{\uparrow} = \downarrow$ and $\bar{\downarrow} = \uparrow$. The simple replacement $1 \rightarrow 3$ in the expression of H_{12} yields H_{23} . In terms of the vacuum state $|0\rangle$, the average and second moment of the transmission probability $\mathcal{T}_{ij}$ are expressed as²³

$$\langle \mathcal{T}_{ij} \rangle = \langle 0 | c_{i\downarrow} c_{i\uparrow} e^{-\tilde{D}_L H} c_{j\uparrow}^\dagger c_{j\downarrow}^\dagger | 0 \rangle, \quad (50)$$

$$\langle \mathcal{T}_{ij}^2 \rangle = \langle 0 | c_{i\downarrow} c_{i\uparrow} b_{i\downarrow} b_{i\uparrow} e^{-\tilde{D}_L H} b_{j\uparrow}^\dagger b_{j\downarrow}^\dagger c_{j\uparrow}^\dagger c_{j\downarrow}^\dagger | 0 \rangle \quad (51)$$

with $\tilde{D}_L = DL$. Here, $c_{i\downarrow} c_{i\uparrow}$, $b_{i\downarrow} b_{i\uparrow}$ and their Hermitian conjugates play a role of the current vertex, where $\uparrow$ and $\downarrow$ correspond to the retarded and advanced sectors, respectively. We see that H is non-Hermitian because $H_{12}^{FB\dagger} = -H_{12}^{FB}$ and $H_{23}^{FB\dagger} = -H_{23}^{FB}$, but it has only real eigenvalues. Equation (51) has not been presented in ref. 23, but we can easily derive it by extending Mathur's argument.

Our task is now reduced to evaluating the correlation functions for the non-random interacting fermion-boson system. Note that H_{12}^{FB} and H_{23}^{FB} annihilate the two-fermion state

$c_{2\uparrow}^\dagger c_{2\downarrow}^\dagger |0\rangle$, while $H_{12}^F c_{2\uparrow}^\dagger c_{2\downarrow}^\dagger |0\rangle = H_{23}^F c_{2\uparrow}^\dagger c_{2\downarrow}^\dagger |0\rangle = (1/2) c_{2\uparrow}^\dagger c_{2\downarrow}^\dagger |0\rangle$. Consequently, the expressions for $\langle g'_m \rangle = \langle \mathcal{T}_{22} \rangle$ and $\langle g'^2_m \rangle = \langle \mathcal{T}_{22}^2 \rangle$ are simplified to

$$\langle g'_m \rangle = \langle 0 | e^{-\tilde{D}_L H_m^B} | 0 \rangle, \quad (52)$$

$$\langle g'^2_m \rangle = \langle 0 | b_{2\downarrow} b_{2\uparrow} e^{-\tilde{D}_L H_m^B} b_{2\uparrow}^\dagger b_{2\downarrow}^\dagger | 0 \rangle \quad (53)$$

with $H_0^B \equiv H_{12}^B + 1/2$ and $H_1^B \equiv H_{12}^B + H_{23}^B + 1$. Equations (52) and (53) indicate that we can evaluate $\langle g'_m \rangle$ and $\langle g'^2_m \rangle$ in the asymptotic regime of $L \gg D^{-1}$ if the low-energy eigenstates of the boson Hamiltonian H_m^B ($m = 1, 2$) are obtained. That is, we need not consider the fermion degrees of freedom in the following argument. This enables us to treat our task in an analytical manner. It should be emphasized that this special simplification arises only in the case that we treat the right-moving conductance g' with $M = 2$ or 3 . In other words, an analytical treatment seems to be difficult for $M \geq 4$.

To evaluate $\langle g'^2_0 \rangle$, we consider eigenstates $|\Psi\rangle$ of H_0^B . We need to obtain the eigenstates having an overlap with $b_{2\uparrow}^\dagger b_{2\downarrow}^\dagger |0\rangle$, and therefore we focus on the Hilbert space spanned by

$$|\psi^n\rangle = \frac{1}{n!(n+1)!} \left(b_{1\uparrow}^\dagger b_{1\downarrow}^\dagger\right)^n \left(b_{2\uparrow}^\dagger b_{2\downarrow}^\dagger\right)^{n+1} |0\rangle \quad (54)$$

with $n = 0, 1, 2, \dots, \infty$. Eigenstates of H_0^B is expressed as $|\Psi\rangle = \sum_{n=0}^{\infty} c_n |\psi^n\rangle$. From the eigenvalue equation $H_0^B |\Psi\rangle = E |\Psi\rangle$, we obtain the recurrence relation

$$(2n^2 + 4n + 2 - E)c_n - n(n+1)c_{n-1} - (n+1)(n+2)c_{n+1} = 0. \quad (55)$$

On the basis of eq. (55), we obtain the continuous eigenstates $|k\rangle$ which satisfy $H_0^B |k\rangle = \frac{1}{4}(1+k^2)|k\rangle$ and $\langle 0 | b_{2\downarrow} b_{2\uparrow} | k \rangle = 1$ with $k > 0$. The orthogonality condition is

$$\langle k' | k \rangle = \frac{8 \cosh\left(\frac{\pi k}{2}\right)}{\pi k \sinh\left(\frac{\pi k}{2}\right)} \delta(k - k'). \quad (56)$$

The derivation of the above result is briefly described in Appendix B. From eq. (56), we observe that the identity operator $\mathcal{I}$ is expressed as

$$\mathcal{I} = \int_0^\infty dk \frac{\pi k \sinh\left(\frac{\pi k}{2}\right)}{8 \cosh\left(\frac{\pi k}{2}\right)} |k\rangle \langle k|. \quad (57)$$

We now evaluate $\langle g'^2_0 \rangle$. Inserting eq. (57) into eq. (53), we obtain

$$\langle g'^2_0 \rangle = \int_0^\infty dk \frac{\pi k \sinh\left(\frac{\pi k}{2}\right)}{8 \cosh\left(\frac{\pi k}{2}\right)} |\langle 0 | b_{2\downarrow} b_{2\uparrow} | k \rangle|^2 e^{-\tilde{D}_L \frac{1+k^2}{4}}. \quad (58)$$

The main contribution to the k -integration comes from the region of $k \ll 1$, in which we can approximate as

$$\frac{\pi k \sinh\left(\frac{\pi k}{2}\right)}{8 \cosh\left(\frac{\pi k}{2}\right)} = \frac{\pi^2}{16} k^2. \quad (59)$$

After the k -integration, we obtain

$$\langle g'^2_0 \rangle = \frac{\pi^{\frac{5}{2}}}{64} \frac{1}{\sqrt{\frac{DL}{4}}} e^{-\frac{DL}{4}}. \quad (60)$$

This result is identical to eq. (32) in the case of $N = 1$ under the replacement $DL \rightarrow s$.

To evaluate $\langle g'_1 \rangle$ in the asymptotic regime, we consider low-lying eigenstates $|\Psi\rangle$ of H_1^B having an overlap with $|0\rangle$.¹⁹ Therefore, we focus on the Hilbert space spanned by

$$|\psi^{n,m}\rangle = \frac{1}{n!(n+m)!m!} \left(b_{1\uparrow}^\dagger b_{1\downarrow}^\dagger\right)^n \left(b_{2\uparrow}^\dagger b_{2\downarrow}^\dagger\right)^{n+m} \left(b_{3\uparrow}^\dagger b_{3\downarrow}^\dagger\right)^m |0\rangle \quad (61)$$

with $n, m = 0, 1, 2, \dots, \infty$. Eigenstates of H_1^B is expressed as $|\Psi\rangle = \sum_{n,m=0}^{\infty} c^{n,m} |\psi^{n,m}\rangle$. From the eigenvalue equation $H_1^B |\Psi\rangle = E |\Psi\rangle$, we obtain the recurrence relation

$$\begin{aligned} \{1 + 2(n+m+1)(n+m+1/2) - E\} c^{n,m} - n(n+m) c^{n-1,m} - (n+m) m c^{n,m-1} \\ - (n+1)(n+m+1) c^{n+1,m} - (n+m+1)(m+1) c^{n,m+1} = 0. \end{aligned} \quad (62)$$

We restrict our attention to the lowest energy branch of the excitation spectrum, which determines the asymptotic behavior of $\langle g'_1 \rangle$. We assume for this branch that $c^{n,m}$ depends on only $n+m$ (i.e., $c^{n+m,0} = \dots = c^{n,m} = \dots = c^{0,n+m}$), which has been confirmed in ref. 19 by a numerical diagonalization of eq. (62). Under this assumption, we rewrite $c^{n,m}$ as $c^{n,m} \rightarrow c_l$ with $l \equiv n+m$. Equation (62) is then reduced to

$$\{1 + 2(l+1)(l+1/2) - E\} c_l - l^2 c_{l-1} - (l+1)(l+2) c_{l+1} = 0. \quad (63)$$

On the basis of eq. (63), we obtain the continuous eigenstates $|k\rangle$ which satisfy $H_1^B |k\rangle = (1 + k^2) |k\rangle$ and $\langle 0|k\rangle = 1$ with $k > 0$. The orthogonality condition is

$$\langle k'|k\rangle = \frac{\sinh^2(\pi k)}{2\pi k^2 \cosh(\pi k)} \delta(k - k'). \quad (64)$$

The derivation of the above result is briefly described in Appendix C. From eq. (64), we observe that the identity operator $\mathcal{I}$ in the restricted Hilbert space is expressed as

$$\mathcal{I} = \int_0^\infty dk \frac{2\pi k^2 \cosh(\pi k)}{\sinh^2(\pi k)} |k\rangle \langle k|. \quad (65)$$

Inserting eq. (65) into eq. (52), we obtain

$$\langle g'_1 \rangle = \int_0^\infty dk \frac{2\pi k^2 \cosh(\pi k)}{\sinh^2(\pi k)} |\langle 0|k\rangle|^2 e^{-\tilde{D}_L(1+k^2)}. \quad (66)$$

Carrying out the k -integration, we obtain

$$\langle g'_1 \rangle = \frac{1}{2\sqrt{\pi}} \frac{1}{\sqrt{\frac{DL}{4}}} e^{-DL}. \quad (67)$$

This result is identical to eq. (19) in the case of $N = 1$ under the replacement $DL \rightarrow s$.

Finally, we evaluate $\langle g'_1{}^2 \rangle$ in the asymptotic regime. To do so, we consider low-lying eigenstates $|\Phi\rangle$ of H_1^B having an overlap with $b_{2\uparrow}^\dagger b_{2\downarrow}^\dagger |0\rangle$. Therefore, we focus on the Hilbert space spanned by

$$|\phi^{n,m}\rangle = \frac{1}{n!(n+m+1)!m!} \left(b_{1\uparrow}^\dagger b_{1\downarrow}^\dagger\right)^n \left(b_{2\uparrow}^\dagger b_{2\downarrow}^\dagger\right)^{n+m+1} \left(b_{3\uparrow}^\dagger b_{3\downarrow}^\dagger\right)^m |0\rangle \quad (68)$$

with $n, m = 0, 1, 2, \dots, \infty$. Eigenstates of H_1^B are expressed as $|\Phi\rangle = \sum_{n,m=0}^{\infty} d^{n,m} |\phi^{n,m}\rangle$. From the eigenvalue equation $H_1^B |\Phi\rangle = E |\Phi\rangle$, we obtain the recurrence relation

$$\begin{aligned} \{1 + 2(n+m+1)(n+m+3/2) - E\} d^{n,m} - n(n+m+1) d^{n-1,m} - (n+m+1) m d^{n,m-1} \\ - (n+1)(n+m+2) d^{n+1,m} - (n+m+2)(m+1) d^{n,m+1} = 0. \end{aligned} \quad (69)$$

Again, our attention is restricted to the lowest energy branch of the excitation spectrum. We assume for this branch that $d^{n,m}$ depends on only $n+m$ (i.e., $d^{n+m,0} = \dots = d^{n,m} = \dots = d^{0,n+m}$), which can be confirmed by a numerical diagonalization of eq. (69). Under this assumption, we rewrite $d^{n,m}$ as $d^{n,m} \rightarrow d_l$ with $l \equiv n+m$. Equation (69) is then reduced to

$$\{1 + 2(l+1)(l+3/2) - E\} d_l - l(l+1) d_{l-1} - (l+2)^2 d_{l+1} = 0. \quad (70)$$

On the basis of eq. (70), we obtain the continuous eigenstates $|k\rangle$ which satisfy $H_1^B |k\rangle = (1+k^2)|k\rangle$ and $\langle 0|b_{2\downarrow}b_{2\uparrow}|k\rangle = -k^2$ with $k > 0$. The orthogonality condition is

$$\langle k'|k\rangle = \frac{\sinh^2(\pi k)}{2\pi \cosh(\pi k)} \delta(k - k'). \quad (71)$$

The derivation of the above result is briefly described in Appendix C. From eq. (71), we observe that the identity operator $\mathcal{I}$ in the restricted Hilbert space is expressed as

$$\mathcal{I} = \int_0^\infty dk \frac{2\pi \cosh(\pi k)}{\sinh^2(\pi k)} |k\rangle \langle k|. \quad (72)$$

Inserting eq. (72) into eq. (53), we obtain

$$\langle g_1'^2 \rangle = \int_0^\infty dk \frac{2\pi \cosh(\pi k)}{\sinh^2(\pi k)} |\langle 0|b_{2\downarrow}b_{2\uparrow}|k\rangle|^2 e^{-\tilde{D}L(1+k^2)}. \quad (73)$$

Carrying out the k -integration, we obtain

$$\langle g_1'^2 \rangle = \frac{1}{16\sqrt{\pi}} \frac{1}{\sqrt{\frac{DL}{4}}}^3 e^{-DL}. \quad (74)$$

This result is identical to eq. (33) in the case of $N = 1$ under the replacement $DL \rightarrow s$.

4. Summary

We have studied electron transport properties in disordered unitary wires of length L in the presence of the channel-number imbalance between two propagating directions. Our attention is focused on the case in which the number of left-moving channels is by m greater than that of the right-moving ones. In this case, m left-moving channels become perfectly conducting and the dimensionless conductances g and g' for the left-moving and right-moving channels, respectively, satisfy $g = g' + m$. First, we have obtained the average $\langle g' \rangle$ and second moment $\langle g'^2 \rangle$ of $g' = g - m$ in the long- L regime by using the exact solution of the DMPK equation. Both $\langle g' \rangle$ and $\langle g'^2 \rangle$ decay exponentially as a function of L . It is shown that their exponential decay becomes faster with increasing m . This behavior can be understood from the fact that the eigenvalue repulsion arising from the perfectly conducting eigenvalue is enhanced

with increasing m . Second, we have employed the M -edge Chalker-Coddington model for the cases of $M = 2$ and $M = 3$, and obtained $\langle g' \rangle$ and $\langle g'^2 \rangle$ in the long- L regime by using the supersymmetry approach. The case of $M = 3$ corresponds to the simplest nontrivial example of the channel-number-imbalanced unitary class. We have shown that the resulting asymptotic forms of $\langle g' \rangle$ and $\langle g'^2 \rangle$ are identical to those obtained from the DMPK equation including the pre-exponential factor.

Appendix A: Derivation of the Scaling Relation

The average of a function $F(\{\lambda_a\})$ is defined as

$$\langle F \rangle = \int_0^\infty d\lambda_1 \cdots \lambda_N F(\{\lambda_a\}) P(\{\lambda_a\}, s). \quad (\text{A}\cdot 1)$$

Using the DMPK equation given in eq. (1), we find that²⁶

$$\begin{aligned} N \frac{\partial \langle F \rangle}{\partial s} &= \left\langle \sum_{a=1}^N \frac{1}{J} \frac{\partial}{\partial \lambda_a} \left\{ \lambda_a (1 + \lambda_a) J \frac{\partial F}{\partial \lambda_a} \right\} \right\rangle \\ &= \left\langle \sum_{a=1}^N \left\{ \lambda_a (1 + \lambda_a) \frac{\partial^2 F}{\partial \lambda_a^2} + (1 + 2\lambda_a) \frac{\partial F}{\partial \lambda_a} \right. \right. \\ &\quad \left. \left. + \lambda_a (1 + \lambda_a) \left(\sum_{\substack{b=1 \\ (b \neq a)}}^N \frac{2}{\lambda_a - \lambda_b} + \frac{m}{\lambda_a} \right) \frac{\partial F}{\partial \lambda_a} \right\} \right\rangle. \end{aligned} \quad (\text{A}\cdot 2)$$

Replacing F by $g' = \sum_{a=1}^N (1 + \lambda_a)^{-1}$ in the above equation, we obtain eq. (15) after straightforward calculations.

Appendix B: Energy Spectrum of H_0^B

As shown in the text, eigenstates of H_0^B satisfying $\langle 0 | b_{2\downarrow} b_{2\uparrow} | \Psi \rangle \neq 0$ are expressed as

$$|\Psi(E)\rangle = \sum_{n=0}^{\infty} c_n(E) |\psi^n\rangle, \quad (\text{B}\cdot 1)$$

where c_n satisfies eq. (55). We obtain the asymptotic form of c_n in the large- n limit adapting the manipulation given by Mathur.²³ We introduce the generating function defined by $f(x) = \sum_{n=0}^{\infty} c_n x^n$. Using eq. (55), we can show that $f(x)$ obeys

$$x(x-1)^2 \frac{d^2 f}{dx^2} + 2(2x-1)(x-1) \frac{df}{dx} + (2x-2+E)f = 0. \quad (\text{B}\cdot 2)$$

It is convenient to rewrite $f(x)$ as $f(x) = (1-x)^\mu g(x)$. If we set

$$\mu = -\frac{1}{2} + \kappa \quad (\text{B}\cdot 3)$$

with $\kappa = i\sqrt{4E-1}/2$ for $E > 1/4$ and $\kappa = \sqrt{1-4E}/2$ for $E < 1/4$, then $g(x)$ is expressed in terms of the hypergeometric function as $g(x) = F(2+\mu, 1+\mu, 2; x)$. The coefficient c_n is expressed as

$$c_n = \frac{1}{2\pi i} \int_C dx \frac{1}{x^{n+1}} (1-x)^\mu g(x), \quad (\text{B}\cdot 4)$$

where C denotes a small contour encircling the origin in the anticlockwise direction and $c_0 = 1$ has been assumed. We employ the integral representation of the hypergeometric function

$$F(a, b, c; x) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)} \int_1^\infty dt (t-x)^{-a} t^{a-c} (t-1)^{c-b-1}, \quad (\text{B}\cdot 5)$$

which is justified when $\text{Re}[c] > \text{Re}[b] > 0$. Substituting this into eq. (B.4) and exchanging the order of the integrations over x and t , we obtain

$$c_n = \frac{1}{\Gamma(1+\mu)\Gamma(1-\mu)} \int_1^\infty dt t^\mu (t-1)^{-\mu} \int_C \frac{dx}{2\pi i} \frac{1}{x^{n+1}} (t-x)^{-2-\mu} (1-x)^\mu. \quad (\text{B}\cdot 6)$$

We here draw the branch cut between $x = 1$ and $x = t$, and take the phase of $(t-x)$ and $(1-x)$ being zero when x lies on the real axis to the left of 1. Deforming the contour C as in ref. 23, we can show that C is replaced by the contour starting from $x = 1$ to $x = t$ above the branch cut and after encircling the point $x = t$ in the clockwise direction, coming back to $x = 1$ below the branch cut. Exchanging the order of the integrations, we obtain

$$c_n = -\frac{1}{\Gamma(1+\mu)\Gamma(1-\mu)} \int_1^\infty dx \frac{(x-1)^\mu}{x^{n+1}} \int_{C_x} \frac{dt}{2\pi i} t^\mu (t-1)^{-\mu} (x-t)^{-2-\mu}, \quad (\text{B}\cdot 7)$$

where we have drawn the branch cut between $t = x$ and $t = \infty$ on the real axis and C_x denotes the contour coming from $t = \infty$ to $t = x$ below the branch cut and after encircling the point $t = x$ in the clockwise direction, going back to $t = \infty$ above the branch cut. Rescaling t as $u \equiv t/x$, we obtain

$$c_n = -\frac{1}{\Gamma(1+\mu)\Gamma(1-\mu)} \int_1^\infty dx \frac{(x-1)^\mu}{x^{n+2+\mu}} \sigma(x) \quad (\text{B}\cdot 8)$$

with

$$\sigma(x) = \int_{C_1} \frac{du}{2\pi i} u^\mu \left(u - \frac{1}{x}\right)^{-\mu} (1-u)^{-2-\mu}, \quad (\text{B}\cdot 9)$$

where C_1 is identical to C_x with $x \rightarrow 1$. Using an analytic continuation, we can show that

$$\sigma(x) = \frac{\mu}{x} F\left(1+\mu, 2+\mu, 2; \frac{1}{x}\right). \quad (\text{B}\cdot 10)$$

Then, we obtain

$$c_n = \frac{1}{\Gamma(\frac{1}{2}+\kappa)\Gamma(\frac{1}{2}-\kappa)} \int_1^\infty dx \frac{(x-1)^{-\frac{1}{2}+\kappa}}{x^{n+\frac{5}{2}+\kappa}} F\left(\frac{1}{2}+\kappa, \frac{3}{2}+\kappa, 2; \frac{1}{x}\right), \quad (\text{B}\cdot 11)$$

where $\mu = -1/2 + \kappa$ has been used. The change of the variable from x to $s \equiv \ln x$ results in

$$c_n = \frac{1}{\Gamma(\frac{1}{2}+\kappa)\Gamma(\frac{1}{2}-\kappa)} \int_0^\infty ds (e^s - 1)^{-\frac{1}{2}+\kappa} e^{-(n+\frac{3}{2}+\kappa)s} F\left(\frac{1}{2}+\kappa, \frac{3}{2}+\kappa, 2; e^{-s}\right). \quad (\text{B}\cdot 12)$$

The above equation indicates that the behavior of the integrand for $s \approx 0$ is important in considering the large- n limit. Therefore, we employ the approximations $(e^s - 1)^{-\frac{1}{2}+\kappa} \approx s^{-\frac{1}{2}+\kappa}$ and

$$F(a, b, c; e^{-s}) \approx \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} + \frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)} (1 - e^{-s})^{c-a-b} \quad (\text{B}\cdot 13)$$

which are applicable when $e^{-s} \approx 1$. Carrying out the s -integration, we obtain

$$c_n = \frac{1}{\Gamma(\frac{1}{2} + \kappa)\Gamma(\frac{1}{2} - \kappa)} \left(\frac{\Gamma(2\kappa)\Gamma(\frac{1}{2} - \kappa)}{\Gamma(\frac{1}{2} + \kappa)\Gamma(\frac{3}{2} + \kappa)} \frac{e^{\kappa \ln n}}{\sqrt{n}} + \frac{\Gamma(-2\kappa)\Gamma(\frac{1}{2} + \kappa)}{\Gamma(\frac{1}{2} - \kappa)\Gamma(\frac{3}{2} - \kappa)} \frac{e^{-\kappa \ln n}}{\sqrt{n}} \right). \quad (\text{B}\cdot 14)$$

If $E > 1/4$, we can set $\kappa = ik/2$ with $k = \sqrt{4E - 1}$. In this case, c_n in the large- n limit is expressed as

$$c_n(E) = \frac{\alpha_k}{\sqrt{n}} \cos \left(\frac{k}{2} \ln n + \zeta_k \right) \quad (\text{B}\cdot 15)$$

with

$$\alpha_k = \frac{4 \cosh \left(\frac{\pi k}{2} \right)}{\pi \sqrt{k} \sinh(\pi k)}, \quad (\text{B}\cdot 16)$$

$$\zeta_k = \arg \left(\frac{\Gamma(ik)\Gamma(\frac{1}{2} - i\frac{k}{2})}{\Gamma(\frac{1}{2} + i\frac{k}{2})\Gamma(\frac{3}{2} + i\frac{k}{2})} \right). \quad (\text{B}\cdot 17)$$

We show that the orthonormalization of $|\Psi(E)\rangle$ is possible when $E > 1/4$. Note that $\langle \Psi(E') | \Psi(E) \rangle = \sum_{n=0}^{\infty} c_n(E') c_n(E)$. Using eq. (55), we can express the partial sum $\sum_{n=0}^M c_n(E') c_n(E)$ as

$$\sum_{n=0}^M c_n(E') c_n(E) = \frac{(M+1)(M+2)}{E - E'} (c_{M+1}(E') c_M(E) - c_M(E') c_{M+1}(E)). \quad (\text{B}\cdot 18)$$

Substituting eq. (B·15) into eq. (B·18) and then taking the limit of $M \rightarrow \infty$, we obtain

$$\sum_{n=0}^{\infty} c_n(E') c_n(E) = \pi \alpha_k^2 \delta(k - k'). \quad (\text{B}\cdot 19)$$

This indicates that $|\Psi(E)\rangle$ can be orthonormalized when $E > 1/4$. In contrast, when $E < 1/4$, the partial sum $\sum_{n=0}^M c_n(E') c_n(E)$ does not converge in the large- M limit even if $E \neq E'$. Hence, the orthonormalization is impossible. We conclude that $|\Psi(E)\rangle$ exists only when $E > 1/4$. It is convenient to use k instead of E . We rewrite the eigenstate as $|\Psi(E)\rangle \rightarrow |k\rangle$ with $E = \frac{1}{4}(1 + k^2)$. Equation (B·19) is then rewritten as

$$\langle k' | k \rangle = \frac{8 \cosh \left(\frac{\pi k}{2} \right)}{\pi k \sinh \left(\frac{\pi k}{2} \right)} \delta(k - k'). \quad (\text{B}\cdot 20)$$

Finally, we note that $c_0 = 1$ means $\langle 0 | b_{2\downarrow} b_{2\uparrow} | k \rangle = 1$.

Appendix C: Low Energy Spectrum of H_1^B

We first consider the low-lying eigenstates of H_1^B satisfying $\langle 0 | \Psi \rangle \neq 0$. Our attention is restricted to the lowest energy branch in which the eigenstates are expressed as

$$|\Psi(E)\rangle = \sum_{n,m=0}^{\infty} c_{n+m}(E) |\psi^{n,m}\rangle, \quad (\text{C}\cdot 1)$$

where c_l with $l = n + m$ satisfies eq. (63). We obtain the asymptotic form of c_l in the large- l limit. We introduce the generating function defined by $f(x) = \sum_{l=0}^{\infty} c_l x^l$. Using eq. (63), we

can show that $f(x)$ obeys

$$x(x-1)^2 \frac{d^2 f}{dx^2} + (3x-2)(x-1) \frac{df}{dx} + (x-2+E)f = 0. \quad (\text{C}\cdot 2)$$

It is convenient to rewrite $f(x)$ as $f(x) = (1-x)^\mu g(x)$. If we set $\mu = i\sqrt{E-1}$ for $E > 1$ and $\mu = \sqrt{1-E}$ for $E < 1$, then $g(x)$ is expressed in terms of the hypergeometric function as $g(x) = F(1+\mu, 1+\mu, 2; x)$. The coefficient c_l is expressed as

$$c_l = \frac{1}{2\pi i} \int_C dx \frac{1}{x^{l+1}} (1-x)^\mu g(x), \quad (\text{C}\cdot 3)$$

where C denotes a small contour encircling the origin and $c_0 = 1$ has been assumed. Using eq. (B-5) and adapting the procedure described in Appendix B, we obtain

$$c_l = \frac{\sin(\pi\mu)}{\pi\mu} \int_1^\infty dx \frac{(x-1)^\mu}{x^{l+\mu+2}} F\left(\mu, 1+\mu, 1; \frac{1}{x}\right). \quad (\text{C}\cdot 4)$$

After changing the variable from x to $s = \ln x$, we replace the hypergeometric function by the approximate expression given in eq. (B-13). Carrying out the s -integration, we obtain

$$c_l = \frac{\sin(\pi\mu)}{\pi\mu} \left(\frac{\Gamma(1-\mu)\Gamma(2\mu)}{\Gamma(1+\mu)\Gamma(\mu)} \frac{e^{\mu \ln(l+1)}}{l+1} + \frac{\Gamma(1+\mu)\Gamma(-2\mu)}{\Gamma(1-\mu)\Gamma(-\mu)} \frac{e^{-\mu \ln(l+1)}}{l+1} \right). \quad (\text{C}\cdot 5)$$

When $E > 1$, we write $\mu = ik$ with $k \equiv \sqrt{E-1}$. In this case, c_l in the large- l limit is expressed as

$$c_l(E) = \frac{\beta_k}{l+1} \cos(k \ln(l+1) + \eta_k) \quad (\text{C}\cdot 6)$$

with

$$\beta_k = \frac{\sinh(\pi k)}{\pi k \sqrt{\cosh(\pi k)}}, \quad (\text{C}\cdot 7)$$

$$\eta_k = \arg \left(\frac{\Gamma(1-ik)\Gamma(2ik)}{\Gamma(1+ik)\Gamma(ik)} \right). \quad (\text{C}\cdot 8)$$

We show that the orthonormalization of $|\Psi(E)\rangle$ is possible when $E > 1$. Note that

$$\begin{aligned} \langle \Psi(E') | \Psi(E) \rangle &= \sum_{n,m=0}^{\infty} c^{n,m}(E') c^{n,m}(E) \\ &= \sum_{l=0}^{\infty} (l+1) c_l(E') c_l(E). \end{aligned} \quad (\text{C}\cdot 9)$$

Using eq. (63), we can express the partial sum $\sum_{l=0}^M (l+1) c_l(E') c_l(E)$ as

$$\sum_{l=0}^M (l+1) c_l(E') c_l(E) = \frac{(M+1)^2(M+2)}{E-E'} (c_{M+1}(E') c_M(E) - c_M(E') c_{M+1}(E)). \quad (\text{C}\cdot 10)$$

Substituting eq. (C-6) into eq. (C-10) and then taking the limit of $M \rightarrow \infty$, we obtain

$$\sum_{l=0}^{\infty} (l+1) c_l(E') c_l(E) = \frac{\pi \beta_k^2}{2} \delta(k - k'). \quad (\text{C}\cdot 11)$$

This indicates that $|\Psi(E)\rangle$ can be orthonormalized when $E > 1$. In contrast, when $E < 1$, we can show that the partial sum diverges in the limit of $M \rightarrow \infty$ even if $E \neq E'$, and thereby

the orthonormalization is impossible. We conclude that $|\Psi(E)\rangle$ exists only when $E > 1$. It is convenient to rewrite the eigenstate as $|\Psi(E)\rangle \rightarrow |k\rangle$ with $E = 1 + k^2$. Equation (C.11) is rewritten as

$$\langle k'|k\rangle = \frac{\sinh^2(\pi k)}{2\pi k^2 \cosh(\pi k)} \delta(k - k'). \quad (\text{C.12})$$

We obtain $\langle 0|k\rangle = 1$ from $c_0 = 1$.

We next consider the low-lying eigenstates of H_1^B satisfying $\langle 0|b_{2\downarrow}b_{2\uparrow}|\Phi\rangle \neq 0$. We restrict our attention to the lowest energy branch in which the eigenstates are expressed as

$$|\Phi(E)\rangle = \sum_{n,m=0}^{\infty} d_{n+m}(E) |\phi^{n,m}\rangle, \quad (\text{C.13})$$

where d_l with $l = n + m$ satisfies eq. (70). We introduce the generating function defined by $f(x) = \sum_{l=0}^{\infty} d_l x^l$. Using eq. (70), we can show that $f(x)$ obeys

$$x^2(x-1)^2 \frac{d^2 f}{dx^2} + x(x-1)(4x-3) \frac{df}{dx} + \{2x^2 + (E-4)x + 1\}f = 0. \quad (\text{C.14})$$

It is convenient to rewrite $f(x)$ as $f(x) = (1-x)^\mu x^{-1} g(x)$. If we set $\mu = i\sqrt{E-1}$ for $E > 1$ and $\mu = \sqrt{1-E}$ for $E < 1$, then $g(x)$ is expressed in terms of the hypergeometric function as $g(x) = F(1+\mu, \mu, 1; x)$. The coefficient c_l is expressed as

$$d_l = \frac{1}{2\pi i} \int_C dx \frac{1}{x^{l+1}} (1-x)^\mu \frac{g(x)}{x}, \quad (\text{C.15})$$

where C denotes a small contour encircling the origin. It should be noted that eq. (C.15) indicates $d_0 = \mu^2$. For $g(x)$, we cannot directly employ the integral representation of the hypergeometric function given in eq. (B.5) when μ is pure imaginary, so we modify $g(x)$ as

$$g(x) = F(1+\mu, 1+\mu, 2; x) - \frac{1-\mu^2}{2} x F(2+\mu, 1+\mu, 3; x). \quad (\text{C.16})$$

Now, we can apply eq. (B.5) to each term in the right-hand side of the above equation. Adapting the procedure described in Appendix B, we obtain

$$d_l = \frac{\sin(\pi\mu)}{\pi\mu} \int_1^\infty dx \left(\frac{(x-1)^\mu}{x^{l+3+\mu}} F\left(\mu, 1+\mu, 1; \frac{1}{x}\right) + (1+\mu) \frac{(x-1)^\mu}{x^{l+2+\mu}} \left\{ F\left(-1+\mu, 2+\mu, 1; \frac{1}{x}\right) - F\left(-1+\mu, 1+\mu, 1; \frac{1}{x}\right) \right\} \right). \quad (\text{C.17})$$

After changing the variable from x to $s = \ln x$, we replace the hypergeometric functions by the approximate expression given in eq. (B.13). Carrying out the s -integration, we obtain

$$d_l = \frac{\sin(\pi\mu)}{2\pi} \left(\frac{\Gamma(1+2\mu)\Gamma(1-\mu)}{\Gamma(1+\mu)^2} \frac{e^{\mu \ln(l+1)}}{l+1} - \frac{\Gamma(1-2\mu)\Gamma(1+\mu)}{\Gamma(1-\mu)^2} \frac{e^{-\mu \ln(l+1)}}{l+1} \right), \quad (\text{C.18})$$

where several higher order terms with respect to μ are neglected.

When $E > 1$, we write $\mu = ik$ with $k \equiv \sqrt{E-1}$. In this case, d_l in the large- l limit is expressed as

$$d_l(E) = \frac{\gamma_k}{l+1} \sin(k \ln(l+1) + \theta_k) \quad (\text{C.19})$$

with

$$\gamma_k = -\frac{\sinh(\pi k)}{\pi \sqrt{\cosh(\pi k)}}, \quad (\text{C}\cdot 20)$$

$$\theta_k = \arg \left(\frac{\Gamma(1 + 2ik)\Gamma(1 - ik)}{\Gamma(1 + ik)^2} \right). \quad (\text{C}\cdot 21)$$

We show that the orthonormalization of $|\Phi(E)\rangle$ is possible when $E > 1$. Note that $\langle \Phi(E') | \Phi(E) \rangle = \sum_{l=0}^{\infty} (l+1) d_l(E') d_l(E)$. Using eq. (70), we can show

$$\sum_{l=0}^M (l+1) d_l(E') d_l(E) = \frac{(M+1)(M+2)^2}{E - E'} (d_{M+1}(E') d_M(E) - d_M(E') d_{M+1}(E)). \quad (\text{C}\cdot 22)$$

Substituting eq. (C·19) into eq. (C·22) and then taking the limit of $M \rightarrow \infty$, we obtain

$$\sum_{l=0}^{\infty} (l+1) d_l(E') d_l(E) = \frac{\pi \gamma_k^2}{2} \delta(k - k'). \quad (\text{C}\cdot 23)$$

This indicates that $|\Phi(E)\rangle$ can be orthonormalized when $E > 1$. In contrast, when $E < 1$, we can show that the partial sum diverges in the limit of $M \rightarrow \infty$ even if $E \neq E'$, and thereby the orthonormalization is impossible. We conclude that $|\Phi(E)\rangle$ exists only when $E > 1$. It is convenient to rewrite the eigenstate as $|\Phi(E)\rangle \rightarrow |k\rangle$ with $E = 1 + k^2$. Equation (C·23) is rewritten as

$$\langle k' | k \rangle = \frac{\sinh^2(\pi k)}{2\pi \cosh(\pi k)} \delta(k - k'). \quad (\text{C}\cdot 24)$$

We obtain $\langle 0 | b_{2\downarrow} b_{2\uparrow} | k \rangle = -k^2$ from $d_0 = \mu^2$.
